FACTORS FOR CONVERTING INCH-POUND UNITS TO INTERNATIONAL SYSTEM (SI) OF METRIC UNITS

The analyses and compilations in this report were made with inch-pound units of measurement. To convert inch-pound units to metric units, the following conversion factors should be used:

## LOW-FLOW CHARACTERISTICS OF LOUISIANA STREAMS

By Max J. Forbes, Jr.

### ABSTRACT

This report presents annual and monthly statistics of low flow for 114 streamflow stations and annual statistics for 245 stations (partial record) at which intermittent measurements of low flow have been made. For continuous-record stations these statistics were calculated using the log-Pearson type III distribution. For partial-record stations the statistics were determined by a regression of discharges at those stations with discharges at continuous-record stations.

### INTRODUCTION

Since 1900, the population of Louisiana has almost tripled. In addition, since then, the economy of the State has changed from almost totally agricultural to a more balanced economy with a large industrial component. This report deals with water, an essential part of our environment that is strongly affected by the stress of people and their activities. Several conditions favor Louisiana in considering its water resources. The State has an annual rainfall of about 60 in.; and a well-distributed network of streams--among them the Mississippi, Atchafalaya, Red, Pearl, Ouachita, and Calcasieu Rivers--can provide large amounts of water for many uses. Nevertheless, wise management of the State's water resources is a key to Louisiana's continued growth. Problems in municipal, industrial, and agricultural water supply; water-pollution control; fish and wildlife management; and recreation call for solutions. An essential prerequisite to solution is knowledge of the location and behavior of water resources.

Although there are problems associated with a surplus of water produced by heavy rainfall and flooding by streams in Louisiana, these problems are generally of a short-term nature. Conversely, shortages or absences of water can extend for long periods of time and can seriously curtail or stop growth. With that problem in mind, this report presents

statistics on the low-flow frequency of Louisiana's streams. These statistics, computed from the samples represented by the station discharges, are characteristics long accepted as indicators of low-flow behavior. Statistics are reported for 114 locations for which continuous records of discharge are available and for 245 locations where low-flow measurements were made intermittently.

Low-flow statistics presented herein include:

1. For continuous-record stations:

- a. The 2-, 10-, and 20-year low flows (annual) for 1, 7, 14, 30, 60, and 120 consecutive days.
- b. The 2-, 10-, and 20-year low flows (monthly) for 1 and 7 consecutive days.

2. For partial-record stations:

The 2-, 10-, and 20-year low flows (annual) for 7 consecutive days.

Two previous reports have presented low-flow information for Louisiana streams. The first (Page, 1963) presented flow duration and annual frequency information for continuous- and partial-record stations plus draft-storage information. A later report (Cook, 1968) presented duration and frequency curves for continuous-record stations.

The information supplied in Page (1963) is extended in this report by the addition of 17 years of record to the annual frequency analysis for continuous-record stations and by the addition of 131 sites to the annual frequency analysis for partial-record stations. The annual frequency information in Cook (1968) is extended by the addition of 11 years of record. Frequency statistics are also calculated by months for continuous-record stations.

Work on the study leading to this report was begun by Richard A. Rohlf, who left the U.S. Geological Survey in 1971. His contributions are gratefully acknowledged.

#### DEVELOPMENT OF FREQUENCY STATISTICS FOR CONTINUOUS-RECORD STATIONS

Low-flow frequency statistics for a stream-gaging site are computed from a distribution of the lowest discharge events, one from each climatic year of the station's record. Figure 1 shows a discharge hydrograph for Pearl River near Bogalusa, La., (station 024895.00) for the climatic year 1973 (April 1, 1972, through March 30, 1973); the lowest 7-day period of flow is delineated. The average flow ( $1,740 \text{ ft}^3/\text{s}$ ) for this period becomes a data point in a distribution of 7-day average flows for all climatic years of record. (See following table.) Using the frequency computational procedure described by Riggs (1972),

recurrence intervals (reciprocals of probabilities) can be computed and plotted to produce a frequency curve. Figure 2 shows frequency curves for 1, 7, and 14 days for Pearl River near Bogalusa. The 2-, 10-, and 20-year statistics on each curve are circled. As an example of interpretation of these curves, an average flow representing 7 consecutive days will be equal to or less than the 7-day 10-year low flow at intervals averaging 10 years in length, or the probability is 1 in 10 that this average flow will be equal to or less than the 7-day 10-year low flow in any one climatic year.

Continuous-record stations with 5 or more years of record were analyzed for the average annual minimum flows for 1, 7, 14, 30, 60, and 120 consecutive days and for the average monthly minimums for 1 and 7 consecutive days, using the "Streamflow Statistics" and "Log-Pearson Type III" computer programs available through the U.S. Geological Survey WATSTORE system.

The computer produces a plot of the log-Pearson type III frequency curve and shows the data-plotting positions produced by the formula  $\frac{(N+1)}{m}$ , where N is the number of nonzero low-flow events and m is the rank of an individual event. In this particular analysis, if the log-Pearson type III curve did not reasonably fit the data, a graphical curve drawn through the data points was used. The log-Pearson type III analysis in most cases gave an acceptable estimate of low-flow values and was used as a technique for rapid production of the 30 relations for each of the continuous-record stations involved. Zero-flow events cannot be analyzed by the log-Pearson type III computational procedure because the logarithm of zero is undefined. To include these meaningful events in the analysis, the WATSTORE computer program uses the following algorithm:

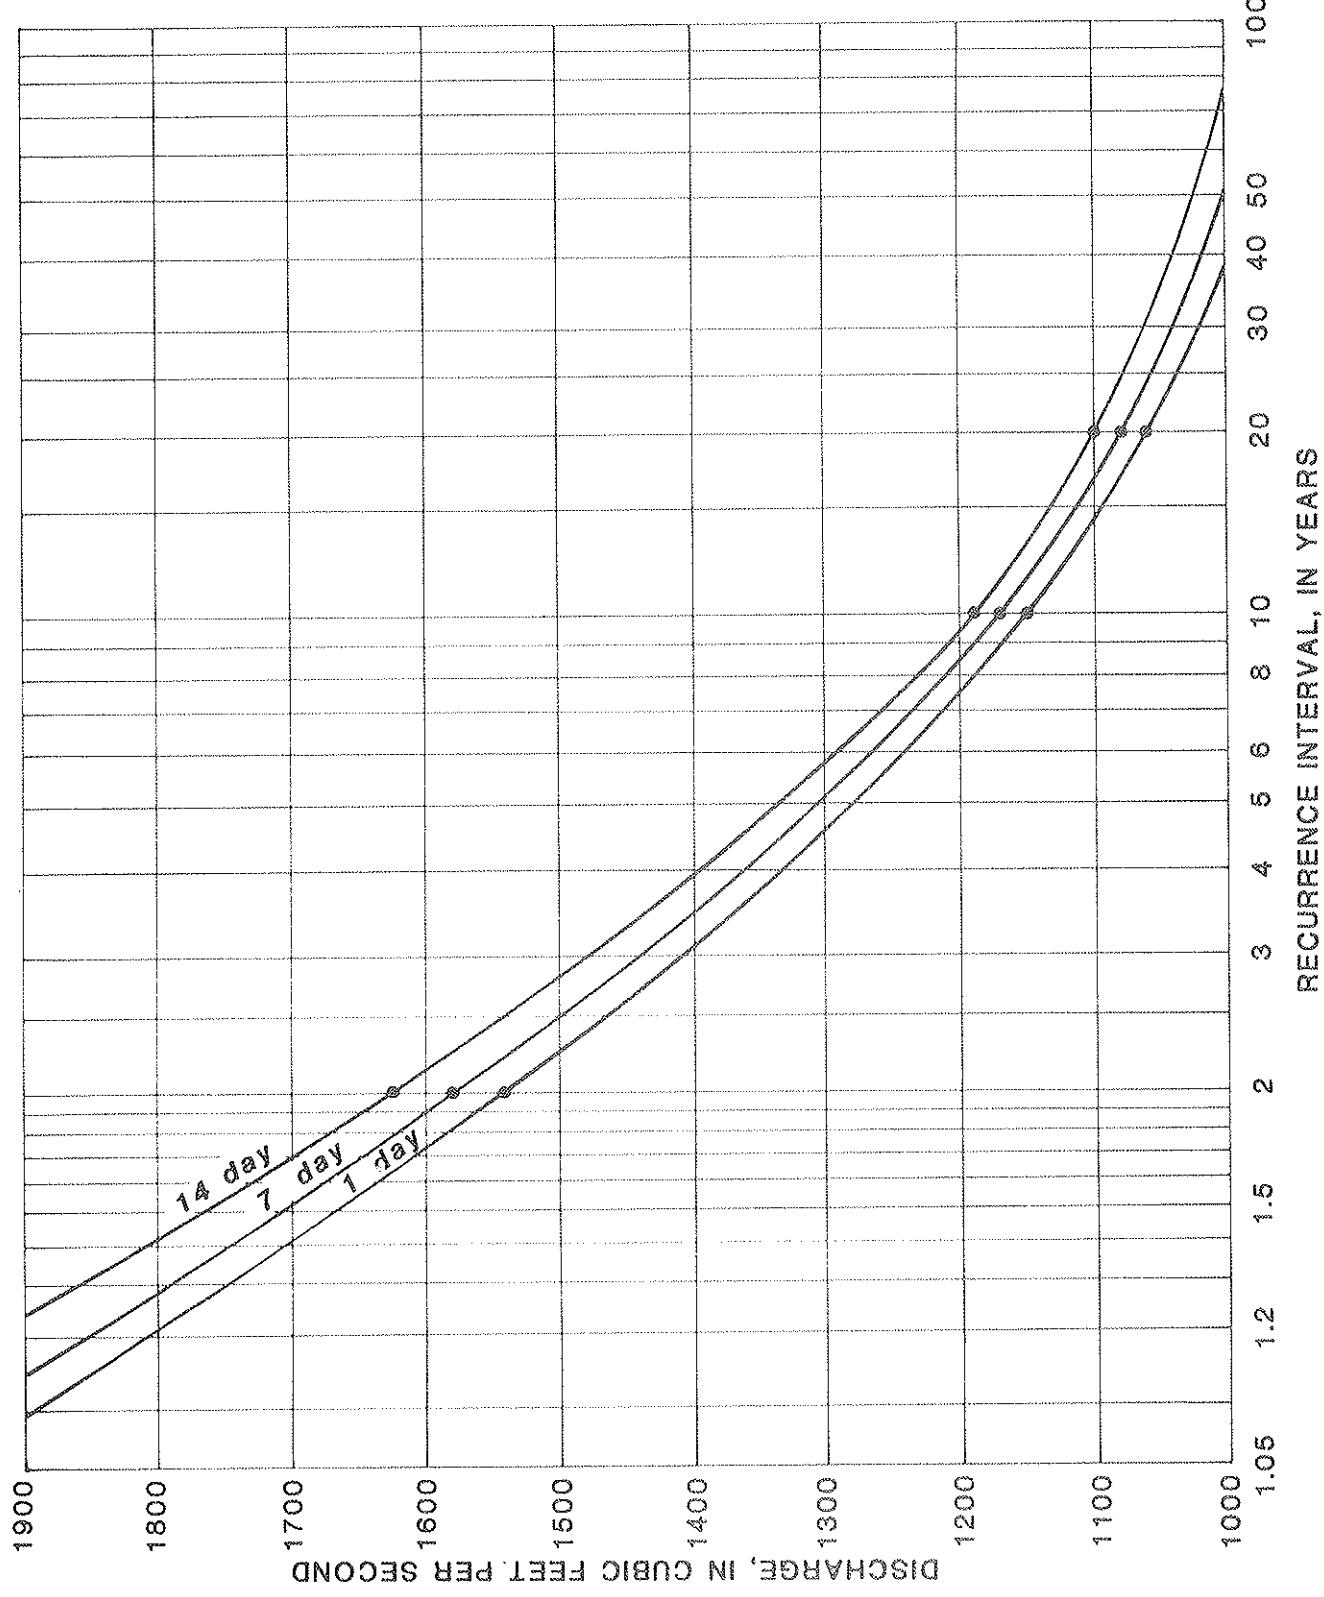

Figure 2.--Low-flow frequency curves (1, 7, and 14 days) for Pearl River near Bogalusa, 1940-75.

$$\text{Adjusted probability} = \left( \frac{n}{N} \times P \right) + \frac{N-n}{N},$$

where n=number of nonzero events,  
 N=total number of events, and  
 P=probability obtained by ignoring zero events.

Plate 1 shows the location of stations that had flow characteristics suitable for a frequency study. Stations are identified by an abbreviated form of the eight-digit downstream-order number. For instance, station number 3695 represents the number 073695.00, in which the first two digits (07) identify the geographic part number, and the following six digits identify the station within the geographic area. A decimal is placed in some numbers to show station numbers carried out to the last two digits (as 3736.5 or 3732.96). Station numbers used in the text and tables are eight digits with a decimal before the last two digits. The numbers are identical to those for the same stations in the Survey data files except that there the decimal is omitted. Low-flow frequency statistics for the stations shown on plate 1 are given in table 1. Three stations in the Sabine River basin (080235.00, 080240.00, and 080242.00) were discontinued in 1967 due to backwater from Toledo Bend reservoir. Although statistics of these sites are no longer directly applicable, they are included as indicators of basin low flow.

A number of continuous-record stations are on streams that are regulated. An evaluation of the regulation (none, slight, moderate, or severe) is included in the station description to aid the user in applying the station statistics to individual problems.

Average standard errors for selected statistics of continuous-record stations were computed in the manner described by Hardison (1969) and are listed below:

| Low-flow statistics | Average standard error |            | Low-flow statistics    | Average standard error |            |  |  |  |

## DEVELOPMENT OF FREQUENCY STATISTICS FOR PARTIAL-RECORD STATIONS

A network of partial-record stations has been operated under Louisiana's low-flow program. Descriptions of these stations are given in table 2; plate 1 shows their location. Most partial-record stations have 10 to 20 base-flow measurements made over a period of at least 5 years. Low-flow statistics may be calculated by relating base-flow measurements to concurrent flows at a continuous-record station for which the low-flow statistics are known and transferring the known characteristics to the partial-record site (Riggs, 1972). This was accomplished by a least square regression using the equation

$$\log Q_p = \log a + b(\log I),$$

in which  $Q_p$ =discharge at the partial-record station (obtained from low-flow measurements),

$I$ =mean daily discharge at the continuous-record station (concurrent with low-flow measurements),

$a$ =regression constant, and

$b$ =regression coefficient.

When a regression equation was obtained, selected low-flow statistics (7-day 2-, 10-, and 20-year values) of the continuous-record station were applied to the equation; and these statistics were computed for the partial-record station. Low-flow frequency statistics for partial-record stations are given in table 3. Average standard errors (for partial-record stations) for these statistics were computed (Hardison, 1969) and are shown below:

| Low-flow statistics | Average standard error |            |
|---------------------|------------------------|------------|
|                     | Log units              | Percentage |
| 2-year-----         | 0.31                   | >75        |
| 10-year-----        | .32                    | >75        |
| 20-year-----        | .32                    | >75        |

For some partial-record stations, no acceptable regression relation could be computed; available measurement data for these stations are included with the station descriptions in table 4.

## INTERPRETATION OF STATISTICS FOR ANNUAL AND MONTHLY LOW-FLOW FREQUENCY

Statistics for annual low-flow frequency have long been accepted as one of the tools of the water planner. These statistics are computed from the lowest consecutive flows in each year of record.

The introduction of statistics for monthly frequency improves the water planner's ability to predict the flow behavior of a stream by

focusing on a given month or group of months. The manner of computation is the same as that described for the annual series, except that minimum events in a given month or group of months for each of the climatic years of record are considered.

The availability of annual and monthly statistics invites comparison and herein lies some difficulty. It might seem reasonable to assume that the 1-day Q<sub>2</sub> statistic for the annual series could be found among the 1-day Q<sub>2</sub>'s for all months. In practice, this is more than likely not the case. Computation of the annual series includes all annual minimum average events. In computation of a monthly series, the daily values that produced the annual minimum-average events are likely to appear in different months or to extend past a monthend. With the possibility of such occurrences, it is safe to assume that annual (statistical) discharges will in most cases be smaller than any of their monthly counterparts. The exceptional cases arise when both annual and monthly statistics are zero or when all annual minimums occur in the same month. Therefore, the monthly (statistical) discharges, which allow more precise definition of stream behavior, generally have the characteristic of being more optimistic when compared with the annual statistic. For example, the annual 7-day Q<sub>10</sub> for Bogue Chitto near Bush is 425 ft<sup>3</sup>/s, which is less than the smallest monthly 7-day Q<sub>10</sub> (435 ft<sup>3</sup>/s for September).

The seemingly pessimistic characteristic of the annual statistic continues to make it useful as an estimate of a "worst possible" situation. Monthly statistics become more valuable when the operating routine of the water user is known. The planner can then make decisions based on water needs and the seasonal occurrence rather than the annual occurrence of minimum flows.

An example of the value of monthly statistics can be found in station 073515.00, Cypress Bayou near Keithville, La. For this station, all annual low-flow statistics through the 60-day period are zero; monthly nonzero statistics are available for 5 months. Conditional use of this stream is possible; annual statistics do not reveal this.
